CCS and the UK's gas grid: The story so far

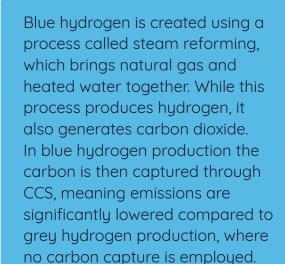

To achieve its net zero targets by 2050, the UK needs innovative technologies to help decarbonise the gas grid. Carbon capture and storage (CCS) is becoming a crucial part of this story, enabling continued use of existing infrastructure while considerably lowering carbon emissions.

What is CCS?

CCS technology stops carbon emissions from reaching the atmosphere, by intercepting them at source. Once captured, ${\rm CO_2}$ is safely transported and locked away deep underground in dedicated storage facilities.

CCS could be a vital piece of the decarbonisation jigsaw puzzle. It offers a way to reduce emissions from hard-to-abate industrial sectors. It also underpins the production of blue hydrogen, which is key to adopting CCS more widely.

4 ways CCS supports the gas grid

Decarbonises existing infrastructure

CCS allows us to continue using gas-fired assets, by capturing emissions at their source, which reduces climate impact without having to replace costly infrastructure.

Delivers a phased transition

By lowering emissions from today's infrastructure, CCS offers a phased and practical route to net zero, while supporting the roll-out of low-carbon alternatives like hydrogen.

Strengthens energy security

Gas offers flexibility that the UK's energy system relies on. CCS lets gas remain part of the mix while reducing its carbon footprint, providing greater reliability during the energy transition.

Scales the hydrogen economy

CCS supports large-scale production of blue hydrogen, which can be blended into the network or used directly in industry, helping to prepare the grid for a hydrogen future.

HyNet North West

Location: North West England and North Wales.

Focus: Led by the HyNet Alliance, it hopes to decarbonise the region's major industries, including the food, ceramics, paper, glass and automotive sectors.

Aim: To transform one of the UK's most energy-intensive areas, reusing depleted reservoirs operated by Eni in Liverpool Bay.

Targets: Removing 10 million tonnes of CO₂ emissions annually after 2030.

Acorn

Location: St Fergus, Aberdeenshire, Scotland.

Focus: Scotland's only CCS project, a collaboration between Storegga, Shell UK, Harbour Energy and North Sea Midstream Partners.

Aim: To establish vital infrastructure for transporting and permanently storing CO₂ in Scotland, supporting the decarbonisation of the Scottish Cluster.

Targets: By 2030, the Scottish Cluster aims to capture and store between 5 and 10 million tonnes of CO₂ per year.

Viking

Location: Humber region (onshore) and the Southern Gas Basin in the North Sea (offshore).

Focus: Led by Harbour Energy, with BP as a non-operated partner, Viking is a major CCS project in the UK's most industrialised and highest-emitting region.

Aim: To provide safe, cost-effective and high-volume storage, while helping the Humber region transition to an area that attracts investments for a low-carbon future.

Targets: To capture, transport and store 15 million tonnes of CO₂ every year by 2035.

East Coast Cluster

Location: Teesside and Humberside.

Focus: A collaboration between Northern Endurance Partnership, Net Zero Teesside and Zero Carbon Humber, the East Coast Cluster wants to remove nearly half of the UK's industrial cluster emissions.

Aim: As well as reducing CO₂ emissions, the Humber and Teesside will benefit from a wealth of green jobs, skills development and supply chain benefits.

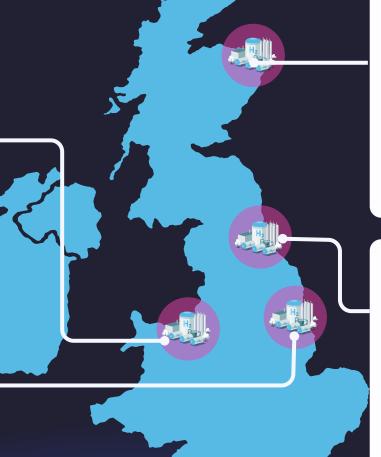

Targets: Potential to capture, transport and store up to 27 million tonnes of CO₂ emissions annually by 2030.

The journey continues

The story of CCS and the gas grid in the UK is rapidly unfolding.

By strategically investing in pioneering CCS projects and integrating this valuable technology as part of its gas network, the UK is not only reducing emissions but securing its energy future too.
